

MULTI DIMENSIONAL ARRAY

- ★ Multi-dimensional array does not originally exist in memory. It is just a perception for the easiment of user.
- ★ We map multi-dimensional array with the memory of 1-D array.
- ★ A multi-dimensional array is an array having more than one dimensions.
- ★ To refer elements in such arrays more, then one subscripts / indices are needed
- ★ The subscripts / indices are based on number of dimensions; e.g. to refer **2D** array, two indices are required. Similarly, for **3D** array, three indices are required and so on.

2-D ARRAY

- * Two dimensional arrays are also termed as **Matrices** in which elements are ordered in number of rows and columns.
- * An example of $m \times n$ matrix (2D array) is

$a_{11} \quad a_{12} \quad \dots \quad a_{1n}$

$a_{21} \quad a_{22} \quad \dots \quad a_{2n}$

$\vdots \quad \vdots \quad \vdots$

$a_{m1} \quad a_{m2} \quad \dots \quad a_{mn}$

- * `int A[3][5];`

A 2-D Array of 3 rows and 5 columns

- * A 2-D Array is an array of 1-D arrays.

- * In the above example, each row(0,1,2) has 1-D array of 5 elements.

- * To refer an element of 2D array, we have to specify the **row number** (first dimension) and **column number** (second dimension).

EXAMPLE OF 2-D ARRAY:

`int A[3][3];`

Columns			
0	1	2	
0	0,0	0,1	0,2
1	1,0	1,1	1,2
2	2,0	2,1	2,2

→ Logical perspective

It is for the easymnt of user. In actual, 2D array does not exist. It only maps with 1-D array.

→ It will first find dimensions.

$$D_1 \text{ (Row)} = 3$$

$$D_2 \text{ (Column)} = 3$$

* Bcz 2D Array originally does not exist, that's why we find dimensions.

then

$$\text{Size} = \text{Row} \times \text{Column}$$

$$= 3 \times 3$$

$$\text{Size} = 9$$

MULTI DIMENSIONAL ARRAY

MEMORY REPRESENTATION :

2
R

- * Like **1D** arrays, multi dimensional arrays are also stored in "Contiguous Locations".
- * Multiply all the dimensions of multi dimensional array to get required number of locations.
- * In array **int A[3][5]**, the total number of locations required are $3 \times 5 = 15$.
- * Similarly in a **3D** array **int[3][5][4]** the required number of location will be $3 \times 5 \times 4 = 60$.

2-D ARRAY MEMORY

REPRESENTATION :

* To map Multi-dimensional array in 1-D array:

→ There are two conventions of storing any two dimensional array in the memory.

(1) Row - Major Order:

The elements of the array are stored on a row by row basis.

(2) Column - Major Order:

The elements of the array are stored on a column by column basis.

Row MAJOR ORDER

- * The elements of the array are stored on a row by row basis, i.e. all the elements of first row, then in the second row, and so on.

	0	1	2
0	(0,0)	(0,1)	(0,2)
1	(1,0)	(1,1)	(1,2)
2	(2,0)	(2,1)	(2,2)

} Logical representation

It will first find Table dimensions:

$$D_1 \text{ (Row)} = 3$$

$$D_2 \text{ (column)} = 3$$

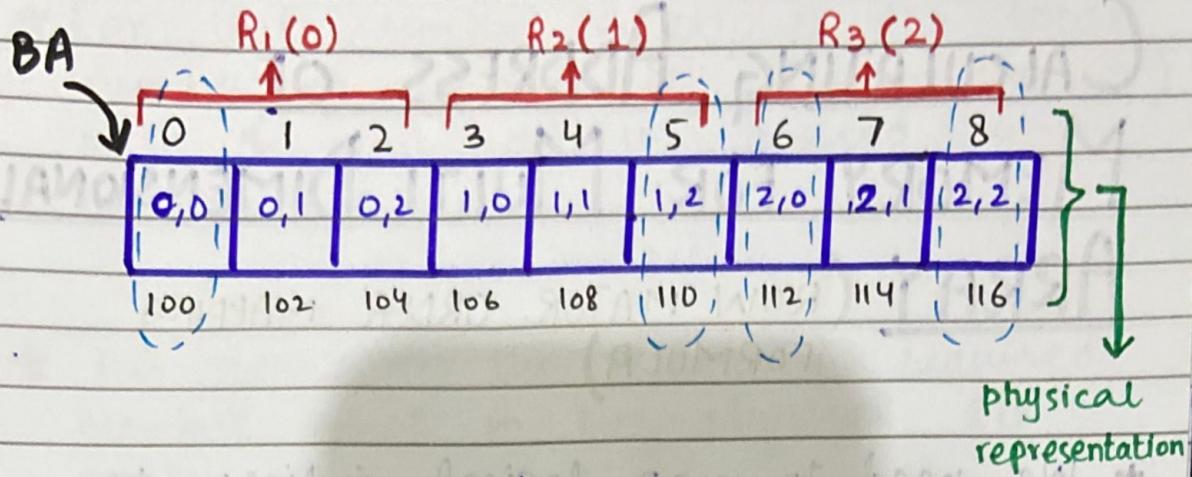

then,

$$\begin{aligned} \text{Size} &= \text{Row} \times \text{Columns} \\ &= 3 \times 3 = 9 \end{aligned}$$

so,

$$\text{Upper Bound} = 8$$

$$\text{Lower Bound} = 0$$

NOTE :

- * In row major order, it will place data in physical memory 'row by row'.
- So,

MD → 1D → Array

$$23 \times (\underbrace{P + cN_i}_{\text{1D to 2D}}) + A8 = (i, j) \text{ address}$$

CALCULATING ADDRESS OF MEMORY FOR MULTI DIMENSIONAL ARRAY (ROW MAJOR ORDER MAPPING FORMULA)

- * We need to map logical indices to physical indices to access a particular element of the array.
- * Suppose a 2D array has u_1 rows and u_2 columns, an element in the i^{th} row and j^{th} column can be obtained by the following formula:

GENERAL FORMULA

$$D_1 = u_1$$

$$D_2 = u_2$$

$$\Rightarrow A[u_1][u_2]$$

$$\boxed{\text{Address}(i,j) = BA + (i \underbrace{u_2 + j}_{\text{Index of 1D}}) \times ES}$$

$\xrightarrow{\text{A}[u_1][u_2] \text{ no. of col. to skip}}$

- * To go to a specific row (i^{th}) we have to skip that specific number of columns (u_2).

* For this, simply multiply the total number of columns u_2 (second dimension) with i and add the desired column number j .

* This gives us the index of required element exist in the physical 1D array.

EXAMPLE (1)

$$i = 1$$

$$j = 2$$

Find address of this 2D in 1D?

$$\text{Address}(\text{index}(1,2)) = \text{BA} + (\underbrace{1 \times 3 + 2}_{\substack{\text{no of columns} \\ \text{which we want} \\ \text{to skip.}}}) \times \text{ES}$$

$$\begin{aligned}\text{Address}(\text{index}(1,2)) &= 100 + (3 + 2) \times 2 \\ &= 100 + 5 \times 2 \\ &= 100 + 10 \\ &= 110\end{aligned}$$

EXAMPLE (2)

$$i = 2$$

$$j = 0$$

$$\text{Address}(A[2][0]) = 100 + (2 \times 3 + 0) \times 2 = 112$$

CAL
ME
(ROW)

EXAMPLE (3)

$$i = 2$$

$$j = 2$$

$$\text{Address } (A[2][2]) = 100 + (2 \times 3 + 2) \times 2 = 116$$

R_0	R_1	R_2
0, 1 100	1, 2 102	2, 0 104
0, 2 106	1, 1 108	2, 1 110

3	4	5	6	7	8
1, 0 112	2, 0 114	1, 2 116	2, 1 118	2, 2 120	

CALCULATING ADDRESS OF MEMORY FOR 3-D ARRAY

(ROW MAJOR ORDER MAPPING FORMULA)

$$A[u_1][u_2][u_3]$$

- To access any arbitrary element i, j, k following mapping can be used

$$A(i, j, k) = BA + (iu_2u_3 + ju_3 + k) \times ES$$

By this, we get mapping of 3D in 1D (Address)

CALCULATING ADDRESS OF MEMORY FOR 4-D ARRAY

(ROW MAJOR ORDER MAPPING FORMULA)

$A[u_1][u_2][u_3][u_4]$

- ★ To access any arbitrary element i, j, k, l following mapping formula can be used:

$$A(i, j, k, l) = BA + (iu_1 u_2 u_3 + ju_2 u_3 u_4 + ku_3 u_4 + l) \times ES$$

GENERALIZED FORMULA (ROW MAJOR ORDER MAPPING FORMULA)

$$A[u_1][u_2][u_3] \dots [u_{n-1}][u_n]$$

* To access any arbitrary element i, j, k, l, \dots, z , following formula can be used:

Address ($A[i][j] \dots [y][z]$)

$$= BA + (iu_1 u_2 \dots u_n + ju_2 \dots u_n + \dots + yu_n + iz) \times ES$$
